Biomedical Informatics

24th Mar 2026

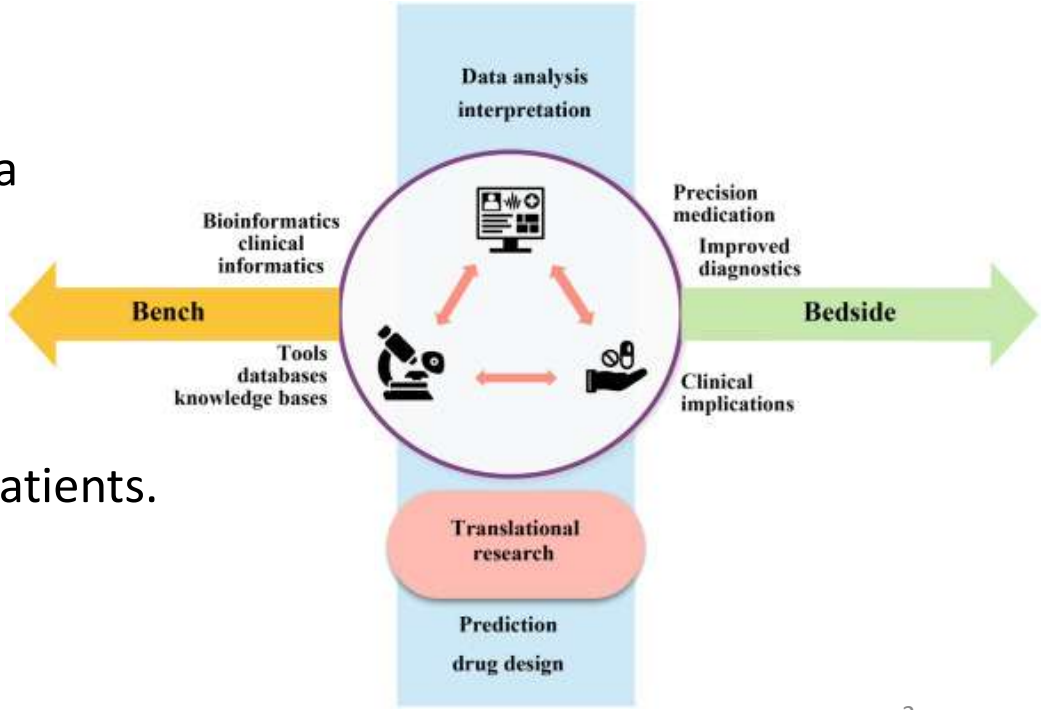
What is translational bioinformatics?

Coined in the early 2010s

Tools and techniques to analyze biological data

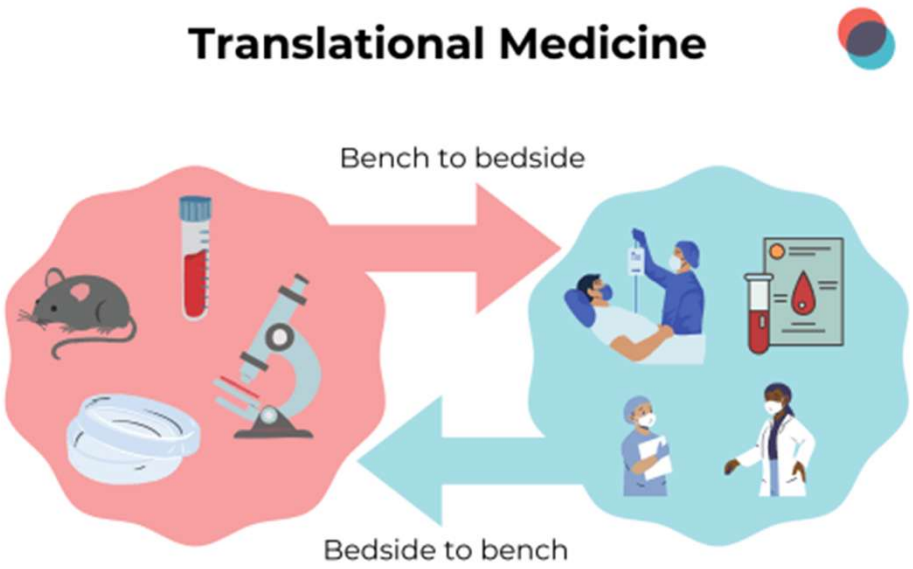
In order to:

- develop new drugs,
- improve disease diagnosis, and
- personalize treatment plans for individual patients.

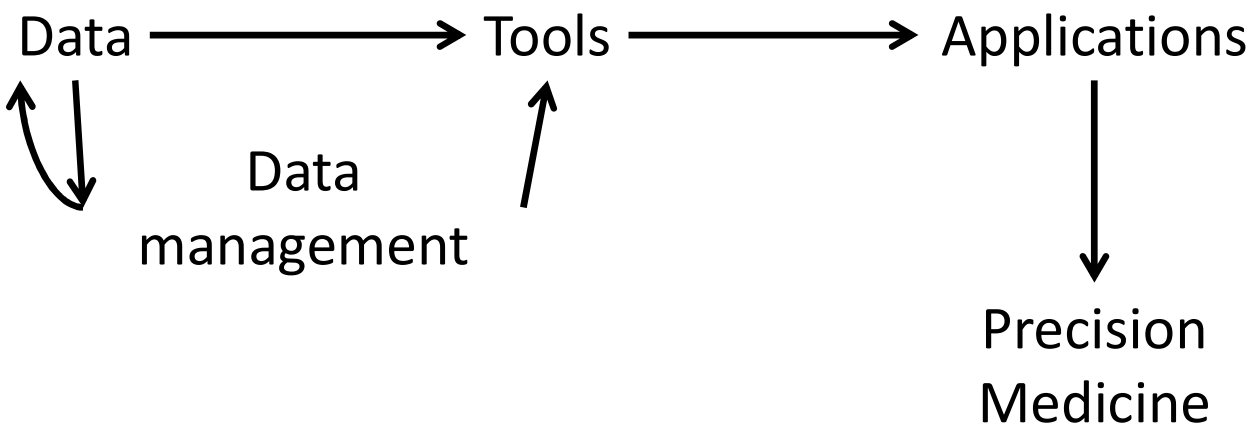


Translational Medicine

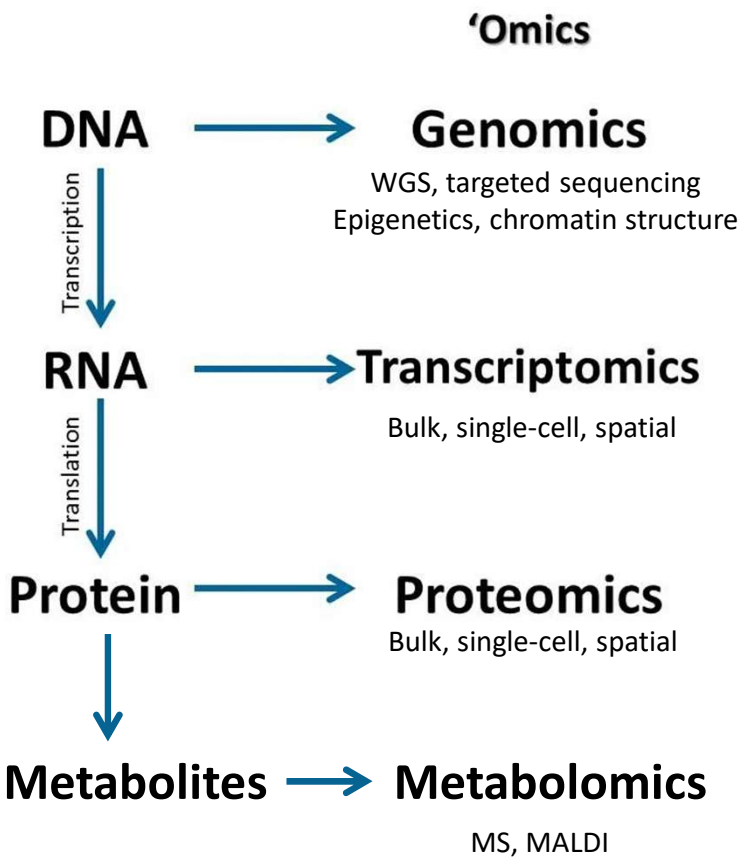
basic science -> clinical research -> application (very slow)



Translational Bioinformatics



What can we measure?



+

Radioimaging → **Radiomics**

Electronic health records

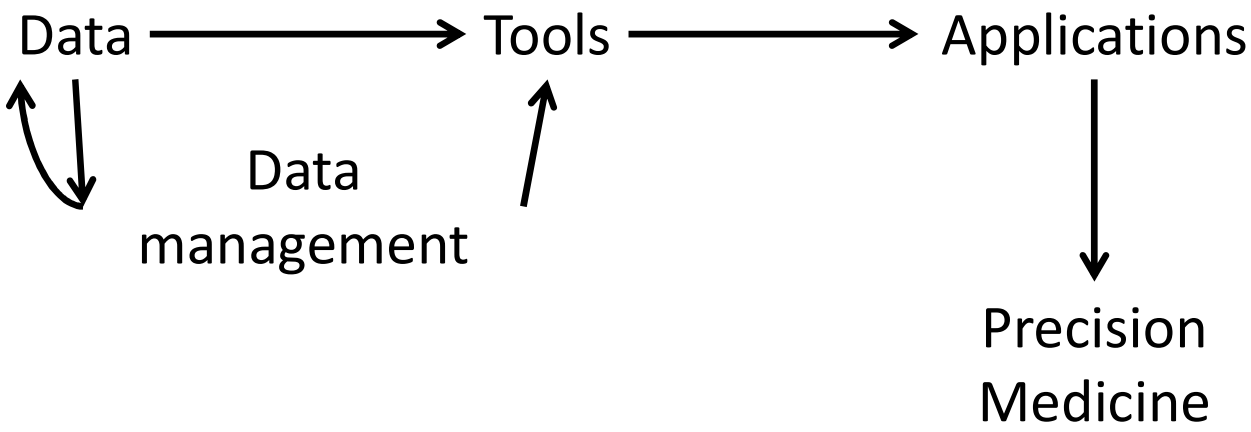
Wearables

Etc.

Characteristics of the data

- Novel technologies $
- Few observations, a great number of parameters
- Multimodal (different technologies combined, on one individual or sample)
- Complex and noisy (heterogenous cohorts, few, often multimorbid patients)
- Privacy concerns!

Translational Bioinformatics



Data management

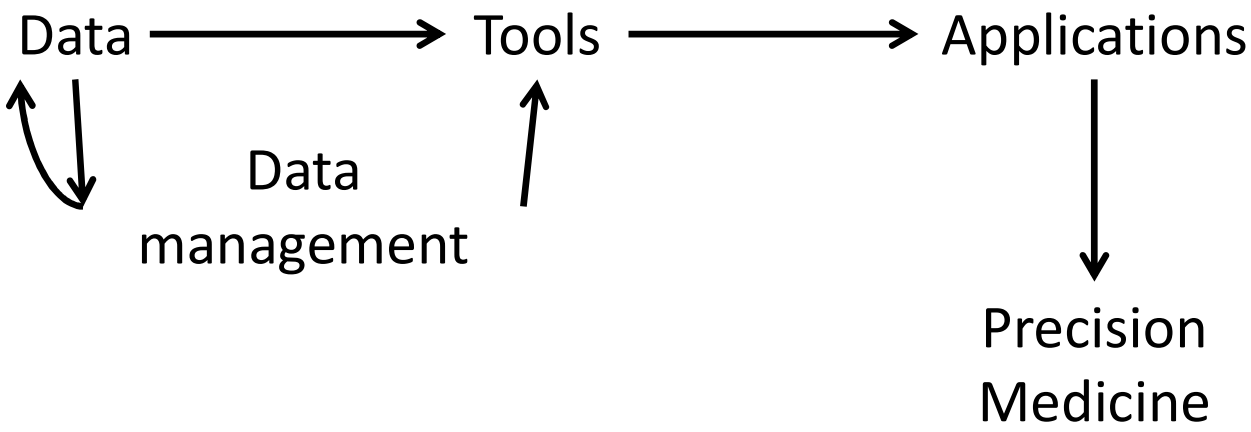
federated

(no data exchange – analysis parameters optmized across the network)

centralized

(data combined into single database)

Translational Bioinformatics



Data analysis in translational bioinformatics

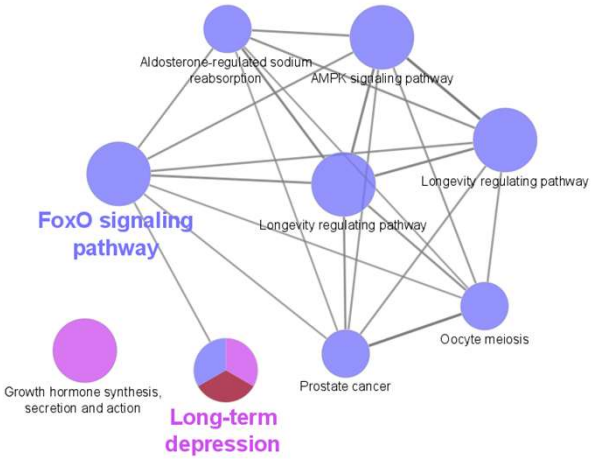
- Highly domain specific
- Traditional statistics
- Machine learning
- Knowledge databases

Big limitation: curse of dimensionality

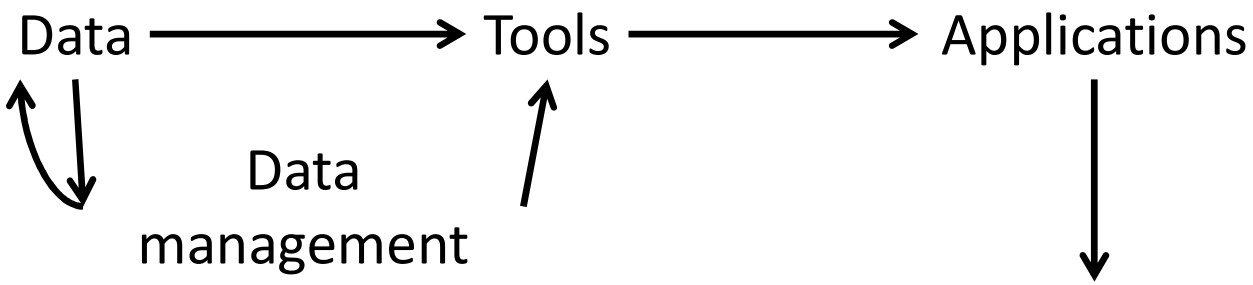
Overcoming the curse of dimensionality

Examples:

- Highly domain specific → Focusing on genes that could be relevant in the disease
- Traditional statistics → Feature selection methods
- Machine learning → Dimensionality reduction
- Knowledge databases → Pathways and gene sets



Translational Bioinformatics

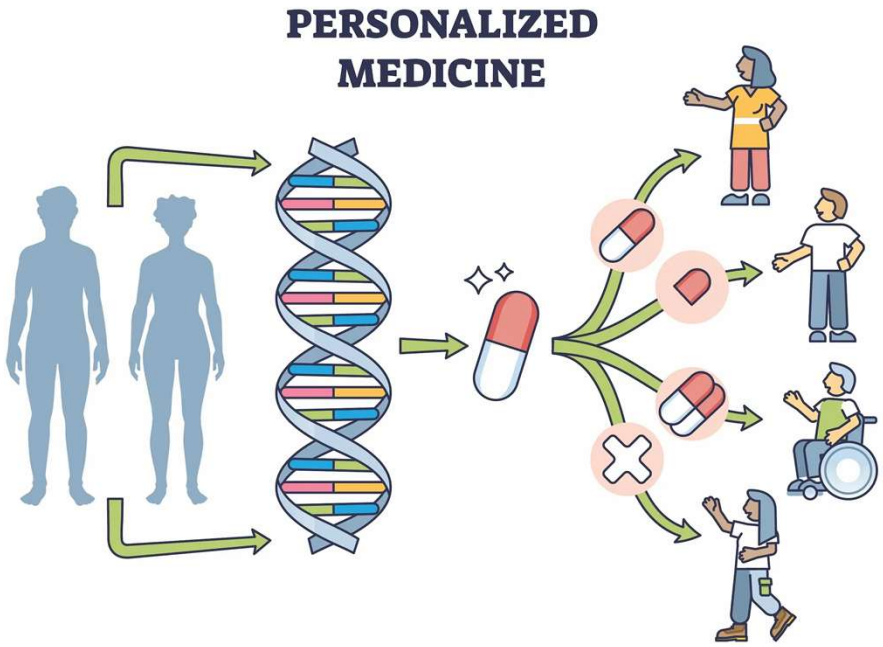


Common applications

Drug Discovery and Development
- Identifying novel targets
- Drug repurposing
- Organoid screening and virtual screening
- Pharmacogenomics

Disease Diagnosis and Prognosis
- Biomarker research
- Prognostic models and classification

Predictive medicine? – Huge trend 10 years ago



Common applications

		Examples
Drug Discovery and Development		
• Identifying novel targets	→	CRISPR-screens
• Drug repurposing	→	Identifying positive side effects from EHRs
• Organoid screening and virtual screening	→	Train models on organoid data to predict *in vivo* response
• Pharmacogenomics	→	Chemotherapy (5-FU) toxicity based on variants
Disease Diagnosis and Prognosis		
• Biomarker research	→	Identify protein in e.g. blood for early diagnosis
• Prognostic models and classification	→	Identify cell-types associated with poor drug response
Predictive medicine	→	Forecast individual disease risks based on genomics

Translational Bioinformatics

Data analytics interface between clinicians and biologists

Driven by
- Cheaper sequencing -> omics
- Machine learning
- More and more data collected

Limitated by
- Ethical considerations
- Privacy issues
- (lacking) Data standards
